Collecting Grape Petioles for Tissue Analysis

Petiole analysis can be used to diagnose or confirm nutrient problems after symptoms are present. More importantly, it is a powerful management tool in determining the nutritional needs of the vines. This is achieved by identifying nutritional shortages or excesses before symptoms develop. Often, petiole analysis will reveal that certain fertilizers being applied are not needed, resulting in a more economical fertilizer program.

Grape petiole nutrient levels (“deficient”, “below normal”, “above normal”, and “excess”) have been established through numerous fertilizer experiments. Because nutrient levels in the petioles can vary throughout the growing season, from petiole to petiole on a vine, and from vine to vine in a field, the standards are valid only for petioles collected during the proper period and from the proper part of the vine. For grapes grown in the Midwest, petiole samples collected between mid-July and mid-August (early veraison) provide the most accurate information based upon established standards.

Petiole samples collected from newly planted grapevines often reflect the conditions the plants were grown under in the nursery. Therefore, it is best to wait until the second growing season or until the vines come into production to assess the nutritional needs through tissue analysis.

Rules to follow when collecting grape petiole samples:
The accuracy of tissue analysis depends upon the accuracy of the petiole sample collection procedure. The following are some general rules that apply to collecting grape petioles:

1. Do not mix different cultivars into one sample! Different cultivars often take up different levels of certain nutrients, or perform better at different nutrient levels. Therefore, if cultivars were mixed into one sample, the results of the analysis may not reflect the actual needs of the plants.

2. If a vineyard is located on a field with more than one soil type, separate samples should be collected for each soil type. Soil survey maps available through your County Extension Office can be used to identify your soil type(s) and the need for this procedure.

3. Plantings that have received different fertilizer applications in the current or previous years should not be combined into a common sample.

4. Avoid sampling from isolated abnormal, weak or unhealthy vines unless they are sampled separately and submitted with a sample collected from healthy vines that are more representative of the planting.

5. Unless specified elsewhere, a sample should consist of 100-150 petioles (150-200 for cultivars with small petioles such as Maréchal Foch). Petioles should be collected randomly from representative vines in the designated sampling area as identified in Rules 1 through 3. Select leaves / petioles that are free from insect, disease and mechanical damage.

6. Remove the leaves and petioles with a downward pull away from the bud located in the leaf axel, then separate the leaf blade from the petiole. (If washing is required, delay removing the leaf blade until after the washing process has been completed.)

7. During the entire sampling and cleaning process, avoid contact with any metal surfaces or tools.

8. Place the collected petioles in a clean paper bag or bag provided by the tissue analysis laboratory, and identify the samples with your name and address, crop, cultivar, field (or sample number) for your reference when you receive the results of the test. Some laboratories may request information on soil type and texture classification, plant growth and yield, current and past fertilizer practices, and spray
materials used (some fungicides contain micro-nutrients) or if foliar feeding has been practiced. Such information aids in the interpretation of the results, and allows the interpreter to make better recommendations. It is always a good policy to contact the laboratory prior to collecting and submitting a sample to determine if it has any specific requirements.

9. Map and identify each sampling area for your future reference.

10. Nutrients to request for testing: “Total nitrogen” (N), phosphorous (P), potassium (K), magnesium (Mg), calcium (Ca), sulfur (S), manganese (Mn), boron (B), copper (Cu), iron (Fe), zinc (Zn), and if available, molybdenum (Mo).

Specific leaf/petiole sampling procedures:

**Grapes:** Petioles are used to determine the nutritional status of grapes. For cultivars with short or small petioles, such as Marechal Foch, collect a sample of 150 to 200 petioles. For a mid-July to mid-August sample, select the most recently fully-expanded leaves from fruit-bearing shoots - typically the 5th to 7th leaf (figure adapted from Univ. of Calif. Publ 4087). From the tip of the shoot, this would generally be the fifth to seventh expanded leaf. Collect no more than one leaf per shoot. Remove the leaf blade and submit the petiole for analysis.

An alternative sampling period for grapes is at full bloom. At this time, collect petioles from leaves located opposite from the basal (first) flower cluster (figure adapted from Univ. of Calif. Publ 4087). Sampling at full bloom can be a suitable assay for nitrogen and boron, but mid-July to mid-August sampling is more reliable for all the other nutrients.

**Cleaning the Sample:**

During the petiole sampling period, it is generally best to allow nature to clean the leaves by collecting them following a heavy rain and before the next pesticide application. However, if the leaves are dirty, or if sprays containing nutrients have been recently applied, the petioles should be rinsed in a mild detergent solution (liquid dish washing detergents or non-ionic spreaders work well) followed by two distilled or deionized water rinses. The leaves with petioles attached should be washed while still fresh, and the whole procedure should be completed in less than a minute to minimize the loss of any mineral nutrients. After rinsing, excess water should be shaken off the leaves, patted dry with clean paper towels, and then remove the leaf blade. Petioles should then be place in a clean paper bag for shipment to the tissue testing laboratory. Some laboratories will wash leaves if requested while others do not, so it is always a good policy to contact the laboratory prior to collecting the sample.
Plant & Soil Analysis Laboratories:

**Iowa:**
A & L Heartland Laboratories  
P.O. Box 455  
111 Linn Street  
Atlantic, IA 50022  
Ph: (712) 243-6933  
http://www.allabs.com/  

AgSource Laboratories-Belmond  
1245 Hwy 69  
Belmond, IA 50421

* Disclaimer Clause: Listing of soil and plant analysis laboratories is not intended to be an endorsement to the exclusion of other laboratories that may offer similar services.*
Many of the commercial laboratories will do an interpretation of the results, but I have observed discrepancies in the sufficiency ranges compared to those used for fruit crops at ISU, or the use of inappropriate ranges based upon the time of sampling. Because of this situation, it is a good idea to have your Extension fruit specialist or mineral nutrition specialist look over the results of your tests. Additional information that will assist them would be information on your soil type, texture and internal drainage classifications; a record of your current and previous fertilizer practices, a listing of list of spray materials applied in the current year prior to collecting the leaf/petiole sample; and any explanation pertaining to the condition of the plants from which the samples were collected.
